

1. A “has-a” relationship refers to a class that contains class member variables. A “is-a” relationship differs by having a class inherit/derive from another existing class.
2. Both the go() and stop() methods will be available to an object of the derived class.
3. Both implementing an abstract method and overriding a method both relate to inheritance by having a subclass derive information from the parent class (superclass). From my understanding, abstract methods do not define the details in the superclass, and instead have the specific logic defined in the subclasses. Overriding a method, on the other hand, does define the method’s function in the parent class, but in the subclasses, new logic is defined, therefore overriding the original method’s function.
4. I believe that both abstract classes and interfaces contain method declarations that have no implementation. Abstract classes are designed to be inherited as they should not represent objects themselves. Interfaces can not be inherited and may only be implemented in a class.
6.
 - a) Abstract method
 - b) An interface
 - c) Roo is required to implement all methods from Wo
 - d) doThis(), doThat(), doNow()
